

CPU Dojo 1

Journey into the ever growing CPU that rules from the centre of the Ultraworld

In the language of your choice create a virtual CPU which will have 2 registers and 16 *items* of memory. Using the list of operations listed below create a program which does the following:

- store the number 100 into register *a*
- add the number 7 to register *a*
- store the value of register *a* into memory address 15
- stop the program

Notes:

- Your program will be stored directly in memory from address 0.
- The CPU's program counter will start at 0 and should increase after each operation by the length of the operation stored at that memory location.
- Notice the length of the operations. An operation with a length of 2 will store a value required by the operation in the next memory address.
- You may want to write some code to inspect the contents of your registers and memory after each iteration of the run loop.

Registers:

- *a*
- program counter

Memory size: 16 *items* in length of non floating point number types only!

Operations:

OpCode	Length	Name	Description
0	1	BRK	Stops the program
1	2	LDA	Load the value in the next memory address into register A
2	2	ADC	Add the value in the next memory address to the value in register A
3	2	STA	Store the value of register A into the memory location specified by the value in the next memory address

The equivalent program in 6502 Assembly:

```
LDA #$64      ; 100 = 64 in Hexadecimal
ADC #$07
STA $15
BRK
```

Try the above assembly in a browser and learn more here: <http://skilldrick.github.io/easy6502/>

MOS 6502

The 6502 processor was massive in the seventies and eighties, powering famous computers like the [BBC Micro](#), [Atari 2600](#), [Commodore 64](#), [Apple II](#), and the [Nintendo Entertainment System](#). Bender in Futurama [has a 6502 processor for a brain](#). Even the Terminator was programmed in 6502.
